Project Summary:

This project builds a Clinical Decision Support (CDS) tool to help patients with musculoskeletal conditions to choose between surgery and conservative care.

Issues:

- Clinicians often lack evidence that is specific to patients
- Shared decision making can be time-consuming
- Treatment outcomes vary from patient to patient

Analytics:

- Apply representative treatment effect profile derived from Dataset A
- Convert outcomes to dollar-value scales using WTP anchors (given) and penalty scaling
- Normalize patient preferences
- Calculate treatment score to recommend Surgery or Conservative Treatment

Relevance:

- Translates raw predictions into clinician-friendly visualizations
- Integrates patient values (WP1-WP5) with treatment effects
- Provides transparent recommendation logic for point-of-care decisions
- Designed for CDS deployment inside clinical workflow

Takehome/Recap:

- Effective CDS tools need to be intuitive and accurate. Our interface combines patient preferences with treatment effects to deliver patient-specific treatment recommendations.
